Evaluation of IL-17D in Host Immunity to Group A Streptococcus Infection

Allen Washington, Jr.,* Nissi Variki,† J. Andrés Valderrama,‡ Victor Nizet,‡,§ and Jack D. Bui*

IL-17D is a cytokine that belongs to the IL-17 family and is conserved in vertebrates and invertebrates. In contrast to IL-17A and IL-17F, which are expressed in Th17 cells, IL-17D is expressed broadly in nonimmune cells. IL-17D can promote immune responses to cancer and viruses in part by inducing chemokines and recruiting innate immune cells such as NK cells. Although bacterial infection can induce IL-17D in fish and invertebrates, the role of mammalian IL-17D in antibacterial immunity has not been established. To determine whether IL-17D has a role in mediating host defense against bacterial infections, we studied i.p. infection by group A Streptococcus (GAS) in wild-type (WT) and Il17d−/- mice. Compared with WT animals, mice deficient in IL-17D experienced decreased survival, had greater weight loss, and showed increased bacterial burden in the kidney and peritoneal cavity following GAS challenge. In WT animals, IL-17D transcript was induced by GAS infection and correlated to increased levels of chemokine CCL2 and greater neutrophil recruitment. Of note, GAS-mediated IL-17D induction in nonimmune cells required live bacteria, suggesting that processes beyond recognition of pathogen-associated molecular patterns were required for IL-17D induction. Based on our results, we propose a model in which nonimmune cells can discriminate between nonviable and viable GAS cells, responding only to the latter by inducing IL-17D. The Journal of Immunology, 2020, 205: 000–000.

We previously found IL-17D to have roles in antitumor and antiviral immunity via induction of the chemokine CCL2 and recruitment of NK cells (14–18). Additionally, we and others have shown that IL-17D induces some overlapping sets of genes downstream of IL-17A, including IL-8 and CCL2 (3, 14). In experimental tumor models, exogenous or tumor-expressed IL-17D was sufficient to cause growth delay or tumor rejection (14, 15). IL-17D is regulated by the oxidative stress sensor NF erythroid–derived 2–like 2 (Nrf2) (16), and we have previously described that oxidative stressors and viral infection activate Nrf2, triggering IL-17D expression and immune cell recruitment (16–18). Il17d−/- mice are consequently more susceptible to murine CMV infection and carcinogen-induced tumors (16, 17).

The role of IL-17D in antibacterial immunity is relatively unexplored in mammals, but studies of IL-17D homologs in fish and invertebrate animal models have suggested a protective role (19–23). In fish, Il17d is expressed constitutively and further increased in response to Gram-negative bacterial challenge in organs such as the skin and head kidney (19, 20); similar responses have been demonstrated in marine invertebrates, such as oysters and amphioxus (22, 23). In addition, both Gram-negative live bacteria and LPS induce Il17d in skin cells of lampreys in vitro (21).

In mammals, IL-17 cytokines such as IL-17A and IL-17F are induced in CD4+ T cells by retinoic acid–related orphan nuclear receptor, RORγt and RORα (24–26); epithelial cell IL-17C is induced in response to Gram-negative bacteria (4, 27). Similarly, IL-17E in epithelial cells is induced upon detecting extracellular hemilysins through succinate (28, 29). In mice, we found IL-17D to be induced by viral infection, constitutively expressed in immunogenic cancer cells, and directly induced by the antioxidant transcription factor Nrf2 (14, 16, 17). It is not clear whether bacterial infection or components induce IL-17D in mammalian systems.

Streptococcus pyogenes, also known as group A Streptococcus (GAS), is a leading Gram-positive human bacterial pathogen associated with a wide range of pathological outcomes, from simple pharyngitis and skin infection, to invasive necrotizing fasciitis and...
toxic shock syndrome, and importantly, to postinfectious sequelae, including rheumatic heart disease and glomerulonephritis (30–32). GAS expresses pore-forming toxins (including streptolysins S and O) and extracellular proteases that can induce cellular damage and organ system dysfunction during invasive infection (30, 33). A robust inflammatory response to GAS infection is catalyzed by release of cytokines by immune cells that sense bacterial components or cellular damage molecules (34, 35). GAS infection also stimulates generation of reactive oxygen species (ROS) (36, 37), a cellular mechanism of inhibition for bacterial replication that simultaneously promotes inflammatory cell death (34, 38, 39). Because ROS are known inducer molecules of IL-17D, we hypothesized that IL-17D would be induced and potentially play a protective role during GAS infection.

Materials and Methods

**Mice**

The University of California, San Diego, Institutional Animal Care and Use Committee approved all animal use and procedures (protocol no. S06201). C57BL/6 and IL-17D-deficient (16, 17) mice were housed in specific pathogen-free conditions prior to use. Mice were between 6 and 12 wk old and were age and sex matched across experiments.

**In vivo GAS murine infection model**

Wild-type (WT) GAS strain 5448 was isolated from a patient with necrotizing fasciitis and toxic shock syndrome (40) and is representative of the globally disseminated serotype M1T1 clone that is the predominant cause of life-threatening invasive GAS infections (41). Mice were injected i.p. with the indicated inoculum of GAS in a total volume of 200 μl PBS. Each inoculum was prepared by growing GAS overnight in Todd–Hewitt broth (THB) and adjusting the concentration according to the spectrophotometric OD 600 reading (35). Inoculum CFU were confirmed by serial dilution plating on Todd–Hewitt broth agar (THA). One-time injection of 200 μg/kg N-acetyl-t-cysteine (NAC) in PBS was conducted 4 h prior to GAS infection. Anti-CCL2 polyclonal Ab or control IgG (R&D Systems) was co-injected with GAS. For survival assessment, mice were monitored at least every 12 h to record the body weight and survey health status including signs of lethargy.

Peritoneal exudate and cells were collected by lavage with 2.5 ml PBS. Biopsies of kidney, spleen, lung, and heart of each mouse were collected to determine GAS burden. The tissues were weighed and homogenized in 1 ml PBS or RPMI medium containing 2% FBS through a 70-μm strainer. Homogenized tissues were serially diluted 10-fold, and 50 or 10 μl from each aliquot were cultured overnight on THA at 36.5°C. The measurement of CFU per gram was determined based on total CFU in 1 ml divided by the weight of organ; samples without a colony were arbitrarily assigned as 1 CFU/ml and divided by the weight of the organ to provide graphable data points.

**In vitro GAS infection of cultured cells**

Heat-killed GAS were prepared by placing bacteria at 65–75°C for 5–10 min; absence of CFU growth was confirmed by plating aliquots on THA. The multiplicity of infection (MOI) of GAS-to-cultured cells (immune and nonimmune cells) was 1:1 unless specified. Peritoneal exudate cells (PECs; ~30% macrophages and ~40% B cells), F244 fibrosarcoma, and HEK293 cells were cultured in RPMI 1640 containing 10% FBS with penicillin and streptomycin and switched to 2% FBS without antibiotics the day before the experiment. PECs were collected by lavage using 2.5 ml PBS or FACS buffer per peritoneum. Cell culture plates were spun at 1500 rpm for 5 min to dislodge contact between GAS and cultured cells. Cells were pretreated for 1 h with either NAC or ammonium pyrrolidine dithiocarbamate (PDTC) at a concentration of 0.6 and 0.4 μM, respectively (Sigma-Aldrich). Final concentration of peptidoglycan was prepared as 1 μg/ml (InvivoGen).

**Flow cytometry experiments**

Percentages of leukocytes within each sample were determined using a BD FACSCanto flow cytometer. CD45 (30-F11) and Ly-6G (1A8) markers were employed to identify neutrophils; CD45 and CD11bmid (M1-70) for monocytes; CD45, CD11bhigh, and F4/80 (BM8) for macrophages; NK1.1 (PK136) for NK cells; CD3 (145-2C11) for T cells; and CD45R (RA3-6B2) for B cells (all from BioLegend). Anti-CD192 (SA203G11) was used to identify CCR2-positive cells (BioLegend). 7-Aminoactinomycin D-positive cells were used to identify dead cells (Calbiochem Research Biochemicals).

**Quantitative real-time PCR**

RNA was extracted using TRIzol (Life Technologies) or by using the Direct-zol RNA MiniPrep Kit (Zymogen). cDNA was synthesized using the High-Capacity cDNA Reverse Transcription Kit (Applied Biosystems); quantitative PCR data were generated using SYBR Green Master Mix (Applied Biosystems) with forward and reverse primers of indicated genes; reaction was run on the One Step Plus Real-Time PCR System (Applied Biosystems). Cycle threshold (Ct) values of Hprt or Gapdh reference gene of the vehicle or nontreated control samples were used in calculating the ΔΔCt to determine the 2^ΔΔCt values. Primer sequences are listed in Supplemental Table I.

**ELISA**

Biopsies of kidney from WT and Il17d−/− mice were weighed and homogenized in 1 ml PBS through a 70-μm strainer. Tissue lysates were prepared by using radioimmunoprecipitation assay buffer (Tebnova) with protease inhibitor and samples within the same experiment was normalized using Pierce BCA Protein Assay Kit (Thermo Fisher Scientific). Protein CCL2 was measured using a Quantikine ELISA Kit (R&D Systems) following the manufacturer’s protocol. Standard curve was generated and applied to calculate picograms per milliliter CCL2, and fold difference was determined over mock infection.

**Cytokine injection**

C57BL/6 mice were maintained under specific pathogen-free conditions. A total of 0.5 μg of IL-17D or IL-17A (R&D Systems) in 250 μl PBS or vehicle in PBS were i.p. injected in each mouse. Bioactivity of these cytokines was confirmed previously in vivo (14). Heat-inactivated IL-17D was prepared by heating at 60°C for 30 min. Mice were euthanized using carbon dioxide, and peritoneal cavity was lavaged several times in total 10 ml PBS containing 1% FBS. Cells were incubated in RBC lysis buffer (BioLegend) and counted using the hemocytometer. To quantitate chemokine transcripts in mesothelial cells, peritoneal wall tissue was minced with scissors prior to the extraction of RNA. To analyze the mesothelial cell composition by flow cytometry, peritoneal wall tissues were minced with scissors and digested with collagenase (Worthington Biochemical) in medium overnight at 36.5°C.

**Statistical analysis**

All statistical analyses were processed through a statistical software package (GraphPad Prism). Kaplan–Meier survival curves were generated and analyzed using the log-rank test to assess statistical significance. CFU data from organ homogenates and lavage were analyzed using the non-parametric Mann–Whitney U test. In vitro GAS incubation experiments were analyzed using the Student two-tailed t test. All p values <0.05 were considered to be significant. The p values are denoted in figures as *p < 0.05, **p < 0.01, and ***p < 0.001.

**Results**

**rIL-17D induces ccl2 and recruitment of innate immune cells into the peritoneum**

We hypothesized that IL-17D promotes rapid immune responses in part by inducing chemokines such as CCL2 and recruiting neutrophils. To establish our in vivo model system, we first tested the response of C57BL/6 WT mice to administration of purified rIL-17D into the peritoneal space. Injection of IL-17D induced significant amounts of Ccl2 in peritoneal wall tissue (i.e., mesothelial cells) within 2 h (Fig. 1A). Other chemokines, such as Cxcl3 and Cxcl7, were also induced significantly after i.p. IL-17D injection (Supplemental Fig. 1A). Injection of rIL-17D also led to recruitment of early innate responders such as neutrophils and monocytes, which express CCR2 (Fig. 1B, Supplemental Fig. 1B, 1C).

Accumulation of neutrophils peaked at 4 h, was induced also by IL-17A, and did not occur with heat-inactivated IL-17D (Fig. 1B, 1D). Additional CCL2 was also induced by i.p. IL-17A injection and led to similar recruitment of cells such as monocytes.
depends on IL-17D for local immunity. Indeed, our results above suggest the kidney may be an organ site that achieve statistical significance (Fig. 2C).

**IL17d**

2

Supplemental Fig. 2A). The higher bacterial burdens in the kidney (Supplemental Fig. 2H, 2I). Because IL-17D can induce chemokines such as Cxcl3, Cxcl2, and Ccl7, and Ccl2 in vivo (Supplemental Fig. 2J, 2K), although we found Ccl2 transcript was significantly greater in recruited WT peritoneal cells compared with those in IL17d−/− mice (Supplemental Fig. 2L).

**Phenotype of kidney after i.p. infection of IL17d**

Having established that nonimmune cells in the peritoneum could respond to IL-17 family cytokines, Notably, the peritoneal wall cells responding to IL-17 family cytokines are likely resident mesothelial cells because we did not detect significant levels of immune cells within the peritoneal wall by flow cytometry (Supplemental Fig. 1G).

II17d−/− mice display slightly compromised responses to bacterial infection

Having established that nonimmune cells in the peritoneum could respond to IL-17D, we next assessed the requirement for IL-17D in antibacterial responses in which the bacteria are introduced into the peritoneum (i.p.). After i.p. infection with GAS, we monitored WT and Il17d−/− mice for survival and weight loss. We observed slightly higher weight loss in II17d−/− mice infected by GAS (Fig. 2A, 2B). We also observed a lower survival rate of II17d−/− mice at the maximum GAS dose tested (5 × 10^7), but this did not achieve statistical significance (Fig. 2C).

Previously we had observed that II17d−/− mice manifest higher viral burden in some organs after murine CMV infection (17). Therefore, we examined bacterial burden in multiple tissues after IL-17D–deficient mice compared with WTs infected with GAS. However, Ab neutralization of CCL2 in WT mice did not lead to higher bacterial burden we saw in II17d−/− kidney and peritoneum (Supplemental Fig. 2F, 2G). Furthermore, blocking of CCL2 in IL-17D−/− mice (Fig. 2A), we surveyed for transcripts of other downstream effectors that could potentially substitute for CCL2 in WT versus II17d−/− kidneys (Supplemental Fig. 2D). Although we found some differences, no single chemokine emerged as clearly responsible for recruiting immune cells in the kidney. In the peritoneum, we found no difference in the absolute numbers of recruited neutrophils and macrophages between WT and II17d−/− mice (Supplemental Fig. 2J, 2K), although we found Ccl2 transcript was significantly greater in recruited WT peritoneal cells compared with those in II17d−/− mice (Supplemental Fig. 2L).

**Viable, but not nonviable, GAS induces IL-17D in nonimmune cells**

Because the response to GAS differed between locations that had relatively high (peritoneum) versus low (kidney) cellularity in immune cells, we explored the induction of II17d−/− in immune versus nonimmune tissues. We performed a short-term ex vivo infection of PECs and compared with in vitro infection of epithelial cell lines from mouse and human origin. At an MOI of 1:1, GAS challenge was sufficient to elicit increases in II17d transcript in a renal epithelial cell line (HEK293) and PECs (Fig. 4A, 4B), Fig. 2D). This induction led to higher Ccl2 transcript and CCL2 protein in WT compared with II17d−/− mice (Fig. 3E, Supplemental Fig. 2F, 2G). Furthermore, we observed a lower survival rate of II17d−/− mice infected with GAS (Supplemental Fig. 2A), we surveyed for transcripts of other downstream effectors that could potentially substitute for CCL2 in WT versus II17d−/− kidneys (Supplemental Fig. 2D). Although we found some differences, no single chemokine emerged as clearly responsible for recruiting immune cells in the kidney. In the peritoneum, we found no difference in the absolute numbers of recruited neutrophils and macrophages between WT and II17d−/− mice (Supplemental Fig. 2J, 2K), although we found Ccl2 transcript was significantly greater in recruited WT peritoneal cells compared with those in II17d−/− mice (Supplemental Fig. 2L).

**Phenotype of kidney after i.p. infection of II17d−/− mice**

Our results above suggest the kidney may be an organ site that depends on IL-17D for local immunity. Indeed, II17d, but not II17a, transcript was induced in the kidney of WT mice infected with GAS at 4 and 24 h after i.p. injection (Fig. 3D, Supplemental

**Viable, but not nonviable, GAS induces IL-17D in nonimmune cells**

Because the response to GAS differed between locations that had relatively high (peritoneum) versus low (kidney) cellularity in immune cells, we explored the induction of II17d−/− in immune versus nonimmune tissues. We performed a short-term ex vivo infection of PECs and compared with in vitro infection of epithelial cell lines from mouse and human origin. At an MOI of 1:1, GAS challenge was sufficient to elicit increases in II17d transcript in a renal epithelial cell line (HEK293) and PECs (Fig. 4A, 4B), Fig. 2D). This induction led to higher Ccl2 transcript and CCL2 protein in WT compared with II17d−/− mice (Fig. 3E, Supplemental Fig. 2F, 2G). Furthermore, we observed a lower survival rate of II17d−/− mice infected with GAS (Supplemental Fig. 2A), we surveyed for transcripts of other downstream effectors that could potentially substitute for CCL2 in WT versus II17d−/− kidneys (Supplemental Fig. 2D). Although we found some differences, no single chemokine emerged as clearly responsible for recruiting immune cells in the kidney. In the peritoneum, we found no difference in the absolute numbers of recruited neutrophils and macrophages between WT and II17d−/− mice (Supplemental Fig. 2J, 2K), although we found Ccl2 transcript was significantly greater in recruited WT peritoneal cells compared with those in II17d−/− mice (Supplemental Fig. 2L).

**Viable, but not nonviable, GAS induces IL-17D in nonimmune cells**

Because the response to GAS differed between locations that had relatively high (peritoneum) versus low (kidney) cellularity in immune cells, we explored the induction of II17d−/− in immune versus nonimmune tissues. We performed a short-term ex vivo infection of PECs and compared with in vitro infection of epithelial cell lines from mouse and human origin. At an MOI of 1:1, GAS challenge was sufficient to elicit increases in II17d transcript in a renal epithelial cell line (HEK293) and PECs (Fig. 4A, 4B), Fig. 2D). This induction led to higher Ccl2 transcript and CCL2 protein in WT compared with II17d−/− mice (Fig. 3E, Supplemental Fig. 2F, 2G). Furthermore, we observed a lower survival rate of II17d−/− mice infected with GAS (Supplemental Fig. 2A), we surveyed for transcripts of other downstream effectors that could potentially substitute for CCL2 in WT versus II17d−/− kidneys (Supplemental Fig. 2D). Although we found some differences, no single chemokine emerged as clearly responsible for recruiting immune cells in the kidney. In the peritoneum, we found no difference in the absolute numbers of recruited neutrophils and macrophages between WT and II17d−/− mice (Supplemental Fig. 2J, 2K), although we found Ccl2 transcript was significantly greater in recruited WT peritoneal cells compared with those in II17d−/− mice (Supplemental Fig. 2L).
Induction of \textit{Il17d} in nonimmune cells was ablated when the bacteria were heat killed (Fig. 4A). In contrast, both alive and heat-killed GAS stimulated similar increases in \textit{Il17d} transcript in PECs (immune cells), which are mostly macrophages and B cells (Fig. 4B). Because live bacteria could replicate, we next asked whether the selective induction of IL-17D by live bacteria was a result of increased burden. We found that throughout the time course of the 3-h assay, there was a ∼6-fold increase in live bacteria (Supplemental Fig. 3A). Therefore, we titrated the amount of alive or dead bacteria to test whether selective induction of \textit{Il17d} by live versus dead bacteria was due to differences in quantity of bacteria. We found that decreasing the amount of live bacteria 16-fold could still induce \textit{Il17d} better than killed bacteria in epithelial and sarcoma cells (Fig. 4C, Supplemental Fig. 3B), but not in PECs (Fig. 4D). In addition, spiking the assay with additional dead GAS did not increase \textit{Il17d} transcriptional responses in renal epithelial cells, although it was sufficient for commensurate increases in the inflammatory cytokine \textit{Tnf} as a control (Fig. 4E). Similar to dead GAS bacteria, the bacterial cell wall component peptidoglycan did not induce \textit{Il17d}, whereas \textit{Tnf} transcript rose after peptidoglycan treatment or with living or heat-killed GAS (Fig. 4F).

**IL-17D induction by viable bacterial requires production of ROS in nonimmune cells**

We previously found that oxidative stress, via the transcription factor \textit{Nrf2}, could induce IL-17D (16). As viable GAS stimulates oxidative stress through ROS production (36, 37, 42), we next tested whether treating the infected cells with an ROS scavenger attenuated the levels of IL-17D induced. We confirmed that IL-17D is induced in epithelial cells infected by live GAS, whereas two different ROS scavengers, NAC and PDTC, independently abrogated the effect (Fig. 5A). Notably, \textit{Il17d} induction in immune cells (PECs) were not affected by ROS scavengers, regardless of whether GAS was alive or dead (Supplemental Fig. 3C). At this early time point, ROS scavengers in the culture medium did not block host cell death induced by GAS cytolytic toxins or have an inhibitory effect on GAS growth during the experiment (Supplemental Fig. 3D, 3E).

To test whether ROS scavenger compromises immune responses to bacterial infection, NAC was injected preceding GAS inoculation. We found significantly higher bacterial burden in the kidney but not in the peritoneum in WT mice (Fig. 5B, 5C). Furthermore, \textit{Il17d} and \textit{Ccl2} transcripts and neutrophil infiltration in the NAC-treated mice were lower compared with control-infected mice (Fig. 5D, 5E).

**Discussion**

To apply swift action to fight off pathogens, immune cells recognize pathogen-associated molecular patterns (PAMPs) through pattern recognition receptors (PRRs) leading to effector activities such as production of cytokines (43–46). Most PRRs can respond to dead organisms and even specific molecular components of pathogens.
Our data suggest an immune trigger that relies on bacterial viability in addition to PAMPs. Indeed, increasing evidence points to a distinction between PAMPs produced by the living versus the dead (47–51). By recognizing molecular by-products produced by viable replicating pathogens, the immune response can discriminate between harmless patterns among the normal microbiota and harmful infection (52, 53). Although we have shown that oxidative stress due to viable infection can elicit one specific cytokine (IL-17D), we envision that a more generalizable paradigm could emerge in which other stress pathways, such as metabolic and proteotoxic stress, could also induce cytokine secretion (54) postinfection by viable, but not nonviable, organisms. Thus, certain immune responses initiate only after the overall stress of infection surpasses a threshold. In this way, rather than passively recognizing a pattern or Ag that the pathogen contains, the host cell must undergo stress to appropriately respond. Indeed, this paradigm was shown to control the expression of NKG2D ligands, which can be induced by genotoxic stress (55–57).

The PRRs that orchestrate the immune response to GAS are not clearly defined (58–60). Although TLR2 recognizes peptidoglycans found in Gram-positive bacteria (including GAS), it is not required for immune responses to GAS (58). TLR13 in macrophages is required to recognize GAS bacterial RNA in mice (61), and TLR9 recognition of GAS DNA is key to host defense against the pathogen (62). Activation may depend on other components as well because C-type lectin receptor expressed by macrophages mediates cytokine production by detecting GAS lipoteichoic acid (63).

GAS is known to induce ROS and oxidative stress caused by invasion-triggered caspases, and ROS production is linked with cell death in macrophages and epithelial cells following GAS infection (36, 37, 42). Attenuated ROS production has been observed in...
epithelial cells infected by adhesion-incompetent or heat-killed GAS (36, 37, 64). We have previously reported that oxidative stress can lead to IL-17D expression via the activation of the antioxidant transcription factor, Nrf2 (16, 17). Altogether, our studies suggest that viable GAS infection induces ROS, leading to oxidative stress and Nrf2 induction, which results in secretion of IL-17D and innate immune responses.

Given that Nrf2 responds to oxidative stress and is critical in protecting cells against ROS-mediated damage, the role of Nrf2 in bacterial immunity is complex (65). For example, in a sepsis model, Nrf2 deficiency results in far higher mortality rate, sensitivity to inflammation by LPS and TNF, and induction of proinflammatory genes (66). In addition to the global changes to the inflammatory activity of Nrf2−/− mice, Nrf2-deficient alveolar macrophages are compromised in phagocytic uptake of microbes such as Pseudomonas aeruginosa (67). In contrast, Gomez and colleagues (68) report that mice lacking Nrf2 had increased phagocytic activity at baseline but had compromised immune activation and increased mortality after lung infection by S. pneumoniae. It is not clear whether this increased mortality is due to insufficient cell-protective antioxidant responses or the lack of IL-17D induction. Although clearly Nrf2 is important for immunity, further studies are needed to clarify the impact of IL-17D in Nrf2-mediated responses.

We demonstrated that Il17d−/− mice are more prone to increased death and weight loss upon opportunistic GAS infection, although with a modest presentation. In addition, the loss of IL-17D resulted in phenotypes limited to some organs such as the kidney, but not in organs such as the spleen and lung. Cytokines in the IL-17 family induce effector molecules that are generally overlapping in similar targets (3, 4, 5). So far, it is known that IL-17A, IL-17F, IL-17E, and IL-17C share at least one receptor subunit, IL-17RA, for signal transduction (2). We speculate that IL-17D is dispensable in spleen and lung because IL-17A is sufficient to confer protection in those organs. In fact, lacking IL-17A in the lung and spleen has been shown to delay and limit neutrophil recruitment postinfection by pathogens (69, 70). Furthermore, although IL-17RA and IL-17RC (receptors for IL-17A/F) are protective in candidiasis, IL-17RE (IL-17C cognate receptor) does not protect against infection (71). These observations suggest that some IL-17 cytokines are redundant in tissues with overlapping expression patterns. Similar to IL-17D, IL-17A promotes neutrophil migration and is generally known to participate in antipathogen immunity. However, IL-17A/F and IL-17C promote LPS-induced toxic shock, whereas IL-17D does not (72–74). Therefore, in addition to overlapping functions of IL-17 cytokines, the degree of inflammation promoted by each may differ by scale. In light of these previous findings, we speculate that the modest effect of IL-17D is attributable, in part, to the complex overlaps in downstream effectors among proinflammatory cytokines and especially those within the IL-17 family.

We measured increases in Il17d and Ccl2 upon in vivo GAS infection of the WT kidney and detected a trend for lower neutrophil infiltration and relatively lower Ccl2 transcript and protein in the kidneys of Il17d−/− compared with WT mice. Because blocking Ccl2 protein did not compromise infiltration or bacterial clearance, we surmise that IL-17D can induce other chemokines that work together to recruit the appropriate immune response, perhaps redundantly. Indeed, rIL-17D induced a plethora of chemokines, including Cxcl3, Ccl7, and Ccl5. We speculate that the fact that the kidney harbors a relatively low ratio of immune cells to nonimmune cells when compared with organs such as lungs and spleen explains its reliance on IL-17D-induced chemokines for antipathogen immunity. Thus, Il17d−/− mice may face greatest disadvantage in warding off bacterial infection in organs dependent on effective recruitment of early active responders. Notably, unregulated IL-17D production in locations that have low levels of resident immune cell could lead to pathologic conditions. Therefore, it is logical to place a checkpoint in nonimmune cells, limiting their production of IL-17D only during live infection, as we have shown. This live/dead checkpoint could serve as a paradigm to regulate immune responses in tissues with low levels of immunity but that may also harbor commensal organisms.
